# Mobile Application

We build reliable mobile apps for iOS and Android, from product development and integrations to store release and long-term support.

# Why clients come to us

A mobile app is rarely just a mobile app. It is part of a wider product, connected to your systems, your users, and the way your business works.

We don't see our role as simply building what is written in a specification. We work alongside our clients to understand what they are trying to achieve, make the technical decisions that support it, and take responsibility for getting the product into the hands of its users.

That means we can help shape the product, build it, connect it to the systems around it, get it through the stores, and continue improving it after launch.

---

# What we do

From the first conversation to the first release and beyond, we take ownership of the technical work required to make the app successful.

### Build

We turn product ideas and requirements into reliable mobile applications. We help choose the right technology and architecture, build the product, and make the technical decisions needed along the way.

### Integrate

A mobile app is only as useful as the systems it works with. We connect it to your existing APIs, databases, authentication, payments, analytics, and third-party services, while helping identify where the wider system may need to change.

### Automate

We put the processes around the product in place as well as the product itself. Automated testing, builds, and deployments make it easier to release confidently and keep improving the app over time.

### Submit & maintain

We take care of the practical work required to get the app live, from store submissions and compliance to release management. Once it is live, we can stay involved — fixing issues, keeping dependencies up to date, and helping develop the product further.

---

## Our Approach

- **Take ownership, not just tickets.** We work to understand the product and the problem behind the requirement, and take responsibility for finding a good technical solution.
- **Consult as well as build.** Our role does not stop at implementation. We challenge assumptions, explain trade-offs, and help clients make decisions about architecture, technology, and product development.
- **Think beyond the app.** Mobile applications are part of a larger system. We consider the backend, integrations, data, infrastructure, and processes that make the product work as a whole.
- **Build for what comes next.** We aim for technology that is practical today and flexible enough to support the product as requirements, users, and technology change.
- **Stay involved.** Launch is not the finish line. We can continue to maintain, improve, and develop the product as your needs evolve.

---

## Frameworks We Use

We use the technology that makes sense for the product rather than forcing every project into the same stack. React Native and Expo are central to many of our mobile projects, with Flutter and native technologies available when they are the better fit.

**Expo, React Native, React, Flutter, Kotlin, Swift, Objective-C, Java**

---

# Apps we've shipped

Real products, live in the App Store and Play Store, built together with the teams behind them.

## Cantilever

A music streaming app that puts the music first, combining curated albums from independent labels with immersive, multimedia liner notes. Built with React Native and Expo, with a Django backend.

## Creative Arrangements

A video platform for music schools, allowing teachers to create multi-instrument tutorials where individual instruments can be controlled independently. Built with Swift and AVFoundation, with Django powering the backend.

## BCI Drivers

A driver app for international cargo shipments, giving drivers real-time visibility of their deliveries and the information they need while on the road. Built with React Native and Expo, with Django and PostgreSQL powering the backend and Azure hosting the platform.

## Bring Cargo Driver

A driver app supporting domestic deliveries across Norway, giving drivers a clear view of goods and transfers throughout the delivery process. Built with React Native and Expo, with Django and PostgreSQL powering the backend and Azure hosting the platform.

## Evjeklinikken

A health and training app for a Norwegian clinic, providing members with personalised onboarding, workout videos, nutrition guidance, and health tracking through a paid subscription. Built with React Native and Expo, with Django on the backend and integrations including Auth0, Mux, and Vipps.
